

IBM Bob Technology Usage in NetShield

Project Title

NetShield – Wi-Fi Security Scanner

Introduction

NetShield is a Wi-Fi security awareness and scanning prototype designed to help users understand potential security risks associated with Wi-Fi networks. The project focuses on presenting security-related information in a simple and understandable interface.

The objective of the project is to create a user-friendly prototype that demonstrates how Wi-Fi security risks can be identified and communicated to users.

Use of IBM Bob Technology

IBM Bob technology was used during the development process of NetShield to support and accelerate the software development workflow.

It assisted in understanding project requirements, improving the structure of the application, generating and refining parts of the code, and identifying possible issues during development.

IBM Bob was particularly useful in the following areas:

1. Development Assistance

IBM Bob supported the development process by assisting with code creation and refinement. It helped in improving the structure and logic of different components of the NetShield prototype.

2. Code Understanding and Improvement

During development, IBM Bob was used to understand existing code and identify areas that could be improved. This helped in organizing the project more effectively and improving the readability of the code.

3. Debugging Support

IBM Bob assisted in identifying possible coding issues and errors during the development process. This helped reduce development time and supported troubleshooting.

4. UI and Application Workflow

The technology was also used to support the planning and improvement of the application's workflow. Suggestions and development assistance helped in creating a clearer and more user-friendly experience.

5. Learning and Development

As a student project, IBM Bob also served as a learning aid. It helped in understanding development concepts, project structure, and approaches to solving technical problems.

Impact on the Project

The use of IBM Bob technology helped make the development process more efficient. It supported the project by reducing the time required for understanding, writing, and improving parts of the application.

Instead of replacing the developer's role, IBM Bob acted as a development assistant that supported the planning, implementation, and refinement of the NetShield prototype.

Conclusion

NetShield demonstrates the development of a Wi-Fi security awareness and scanning prototype with the support of modern AI-assisted development technology.

IBM Bob contributed to the development process by assisting with code understanding, development, debugging, and project improvement. Its use helped improve productivity and supported the overall implementation of the project.
